AM TO NOT OT. MA

Am. To. Q. No:- 1 (a)

Subnet Mask in CIDR is,

$$8 + 9 = 17$$

19.0.0.0 /17

Am. To. Q. No:- 1 (b)

The 1st and Last numbers are Network IP address and the Broadcast IP address, so any thing in between these 2 can be subnets.

Binary:-

Network IP:- 00010011 00000000 00000000 00000000

Broadcast IP:- 00010011 11111111 11111111 11111111

Sub: \_\_\_\_\_

Day

Time: \_\_\_\_\_

Date: / /

So, we can see that

Decimal:-

Network IP:- 19. 0.0.0

Broadcast IP:- 19. 255. 255. 255

So, The subnets will be in between Network and Broadcast IP.

Ans. To Q. No:- 455

Hence, 112.140.132.173 is from class A. So the host is of  $2^{24}$ . From the question we can see that  $(22-8)=14$  bits are used for the subnet, so,  $2^{14}-2=16384-2=16382$  subnets are possible with in the network.

Ans. To Q. No. 3

Using NAT a private IP can get access to outside networks.

In the question host: 172.16.10.5 and 172.16.10.7 are requesting to a web server 156.147.26.84. So at first the

request will go through NAT, where NAT will incorporate the Real IP of the ISP to the request packet source IP and replace the ISP's real IP with the host's private IP.

The NAT will also insert an Index number to each of these hosts header. The Index will correspond to the private IP in the

Sub: \_\_\_\_\_

Time: \_\_\_\_\_

Date: / /

a table which NAT has. The Index  
will be stored in the TPDU Headers  
port address, Since there are 6 bits  
empty there.

Now, After the incorporation of the real IP  
the packet gets all the real IP privileges,  
and can be easily be routed to the  
web server. When the web server will send a reply packet  
to the NAT, the NAT will check the  
destination IP which is the real IP of the  
ISP and the Index value. Then it will  
compare it with the Index of the NAT  
table and send the packet to its corresponding  
hosts.

—X—

Ans To Q No. 1

$T_{AB} + B_N = 10 + 8 = 18 \text{ ms}$

$T_D + D_N = 19 + 9 = 28 \text{ ms}$

$T_G + G_N = 16 + 15 = 31 \text{ ms}$

$T_H + H_N = 18 + 11 = 29 \text{ ms}$

So, From the above calculation T will

choose to ~~do~~ send the packet to B,

since it will take the shortest time.

## Ans To Q. No. 5

112.130.160.254/20 is of class A and ~~the~~  
12 bits are used for the subnet.

So,  $2^{12} - 2 = 4094$  subnets. and  $2^{12} - 2 = 4094$

hosts are under each ~~sub~~ subnet.

Binary :-

Network :- 0111 0000 0000 0000

1st Subnet :- 0111 0000 0000 0000
