Name: Md. Rokibul Hasan

ID: 2019-1-60-114

Course: CSE-405

Section: 03

Examination: Midterm 1

Date: 17/11/2021

Semester: Fall - 2021

Instructor: MAR

Ans: to the Q: No: (1)

Here,

B: 01000011

D: 11111000

Flag: 01111110

Esc: 10001111

Given data is,

B Esc Esc Flag Flag D

Now we use "Bit stuffing" method:-

$$\begin{array}{ccccccccccc} 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ \hline & & & & & & & & & & & & & & & & & & & & & & & & & & & \\ \text{Flag} & & & & & & & & & & & & & & & & & & & & & & \text{sb} & & & & & \end{array}$$

$$\begin{array}{ccccccccccccccccccc} 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 0 \\ \hline & & & & & & & & & & & & & & & & & & & & & & & & & & & & & & & & & & \\ \text{sb} & & & & & & & & & & & & & & & & \text{sb} & & & & & & & & & & & & & & & & & & & \text{Flag} \end{array}$$

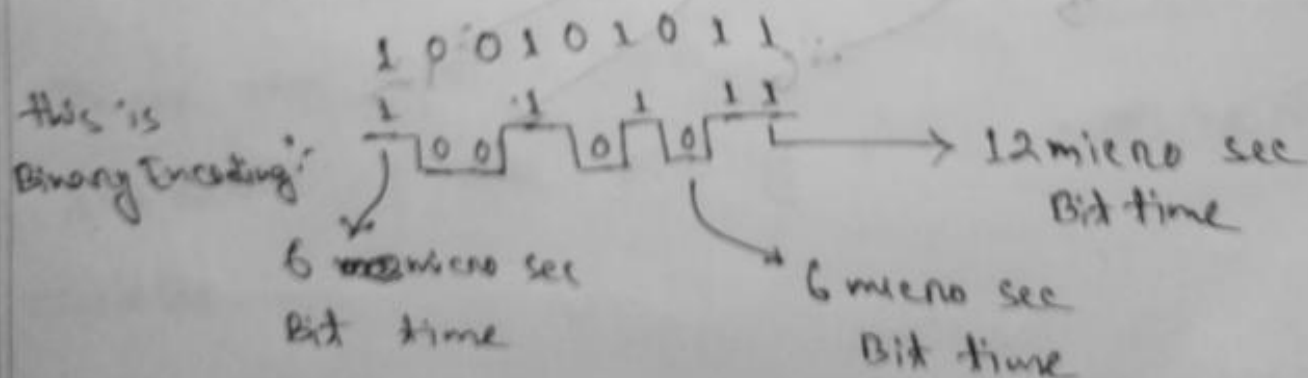

Here, sb \rightarrow stuffed Bit.

so this

Ans. to the Q: No: 2

In Physical layer coding violation, nodes determine the boundary of a frame by sensing the Bit time. In data for '1' we use a high voltage and '0' we use a low voltage. Assume that voltage is 5. Then in a frame we usually use half of that voltage. That's 2.5. The nodes sense this violation and determine it is frame.

Given bit sequence,

If the first bit is high voltage and its

value is 6 then If in the bit sequence there are any consecutive high voltage then it will be 12, 18, 24 - etc. Same goes for low voltage. And this is the multiplier of the specific voltage which value is 6 ^{volt.} ~~micro~~ sec. This value isn't fixed. In physical violation the bit sequence will be:-

1 0 0 1 0 1 0 1 1

Ams: to the Q.No: 5

Complete petri net model for
mutual Exclusion

Ans: to the Q: No: (4)

Set of A = $\{0, 1, 2, 3\}$

Set of B = $\{0, 1, 2, 3, 4, 5, 6, 7\}$

After collision A and B will pick a number from set and multiply it by 512 Bit time.

If A pick 1 then it will wait $(1 \times 512) = 512$ Bit time. If it pick 2 then it will wait $(2 \times 512) = 1024$ Bit time.

For A and B there are 4 same value.

$\{0, 1, 2, 3\}$. So if A and B both pick the same number at the same time then there will be consecutive collision.

Because the wait for an exact same time and after that they will transfer

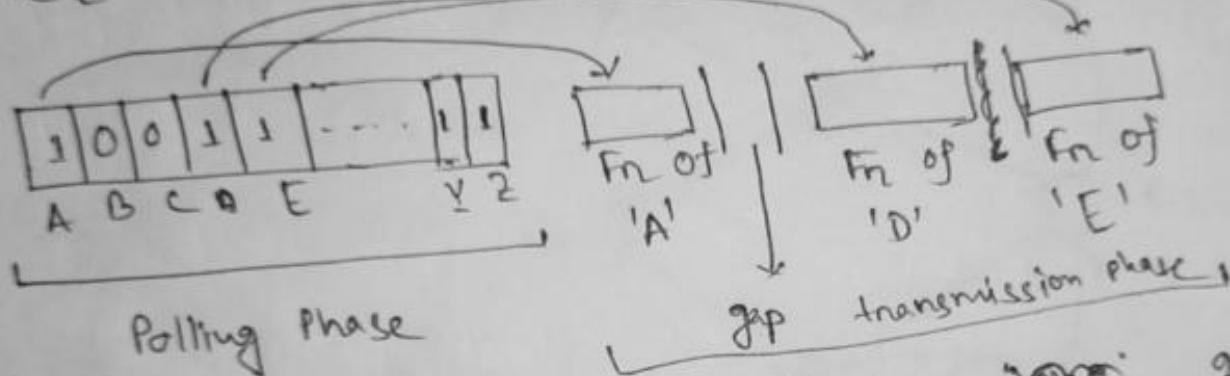

data at the same time. So there will be collision for 4 elements, which are $\{0, 1, 2, 3\}$.
If 'E' also gets into collision then 'A' and 'B' should pick different value like
A can pick '0 to 3' and 'B' can pick
'4 to 7' randomly. Then there will be no collision between 'A' and 'B'. So 'E' can get 1st collision with them.

Ans: to the q: No:- 3

Here, propagation delay is $9 \mu\text{sec}$.

Total nodes = 26.

Here number of Host = 26.

Here 'E' knows there will be ~~gap~~ gap before him. So, it counts that and knows when he can transfer the data.

There are ~~prop~~ 26 nodes. So the minimum duration of the polling phase will be $= (26 \times 9) = 234 \mu\text{sec}$.
